What factors determine the capacitance of a capacitor?

There are three basic factors of capacitor construction determining the amount of capacitance created. These factors all dictate capacitance by affecting how much electric field flux (relative difference of electrons between plates) will develop for a given amount of electric field force (voltage between the two plates):

What factors affect capacitor construction?

One relatively easy factor to vary in capacitor construction is that of plate area, or more properly, the amount of plate overlap. The following photograph shows an example of a variable capacitor using a set of interleaved metal plates and an air gap as the dielectric material:

How do you find the capacitance of a capacitor?

Q = CV Here the term C is known as Capacitance. Does the Capacitance depend upon the Voltage applied across the Capacitor? You might answer yes. But it's not correct. Capacitance only depends upon the physical dimension, dielectric and geometry of Capacitor. In fact the value of Capacitance for a parallel plate Capacitor is given as C = E0ErA/d

How does plate area affect capacitance?

These factors all dictate capacitance by affecting how much electric field flux (relative difference of electrons between plates) will develop for a given amount of electric field force (voltage between the two plates): PLATE AREA: All other factors being equal, greater plate area gives greater capacitance; less plate area gives less capacitance.

Can a capacitor be fixed or variable?

A capacitor can be made variablerather than fixed in value by varying any of the physical factors determining capacitance. One relatively easy factor to vary in capacitor construction is that of plate area, or more properly, the amount of plate overlap.

What is the dissipation factor of a capacitor?

The dissipation factor of a capacitor is the power losswhen AC is applied through the capacitor. This power is either absorbed by the dielectric material or internal/external resistance. Externally,the leads,pads,and solder all lead to an increase in resistance.

A. TDK uses the Arrhenius model (revised by Prokopowicz and Vaskas) to describe failure caused by systematic degradation. This model assumes that the degradation of the dielectric of the capacitor depends both on the temperature and the applied voltage. Basically these are stress factors placed on the system and are collectively called Acceleration Factors.
