How does a liquid cooling system affect the temperature of a battery?

For three types of liquid cooling systems with different structures, the battery's heat is absorbed by the coolant, leading to a continuous increase in the coolant temperature. Consequently, it is observed that the overall temperature of the battery pack increases in the direction of the coolant flow.

What is a power battery pack?

A power battery pack is composed of 10 lithium-ion power battery cells, and the arrangement is shown in Fig. 2. The volume of the box is 180 mm  $\times$  140 mm  $\times$  247 mm, and there is a 5-mm gap between the battery and the battery. The geometric modeling of the whole battery cooling system was established by the SCDM software.

Why is indirect liquid cooling used in power battery pack?

Considering that the indirect liquid cooling method is adopted in this power battery pack, the natural convection heat transfer between the battery and the external environment and the radiation heat transfer (which contributes to a small proportion) can be neglected.

What is the temperature distribution of power battery pack based on reference design?

The temperature distributions of the power battery pack based on the reference design are shown in Figure 10. At the end of the discharge, the temperature of the upper battery module was higher, the heat distribution of the battery module 7 was more concentrated, and the maximum temperature approximately reached 43.4  $^{\circ}\text{C}$ .

What is the maximum temperature of a battery pack after discharge?

After the battery is fully discharged, the maximum temperatures of the battery pack under three different coolant pipeline topologies were 39.59  $^{\circ}\text{C}$ , 36.72  $^{\circ}\text{C}$ , and 32.34  $^{\circ}\text{C}$ , respectively.

How does a battery module liquid cooling system work?

Feng studied the battery module liquid cooling system as a honeycomb structure with inlet and outlet ports in the structure, and the cooling pipe and the battery pack are in indirect contact with the surroundings at 360  $^{\circ}\text{C}$ , which significantly improves the heat exchange effect.

Prior to the experiment, the battery pack is charged at constant current of 12.8 A (1C) to 33.6 V (cut-off voltage), then charged at constant voltage (current below 0.05C). Finally, after being left for an hour, the fully charged battery pack is discharged at different DRs. The experimental and numerical results of battery pack

A hybrid BTMS combines passive and active techniques to achieve a higher level of performance than either approach alone. BTMSs may be used, depending on the situation, to raise or decrease the battery pack's temperature. This work focuses on cooling BTMSs since the greater temperature of LIB is linked to significant issues.
