How do you charge a battery using constant-current/constant-voltage (CC/CV)?

By Irena Zhuravchak and Volodymyr Ilchuk | Tuesday, June 27, 2023 Charging a battery using the constant-current/constant-voltage (CC/CV) method involves using the constant current in the initial state of charging and then switching to constant voltage in the later stages of charging, when the battery reaches the set charge level.

What is the maximum voltage a lithium ion battery can charge?

The charging under constant current-mode continues until the whole battery voltage passes to a maximum allowed voltage, which is 4.2 Ns, where "Ns" is the unit that corresponds to the number of balanced cells in series. However, for the Li-ion batteries, 4.20 Vis the highest voltage that can be used [6].

What are the charging algorithms for lithium-ion batteries?

Abstract: This paper presents the overview of charging algorithms for lithium-ion batteries, which include constant current-constant voltage (CC/CV), variants of the CC/CV, multistage constant current, pulse current and pulse voltage. The CC/CV charging algorithm is well developed and widely adopted in charging lithium-ion batteries.

How to charge a lithium ion battery?

Previous studies have intensively discussed several methods for charging Lithium-ion batteries. The most practiced method is constant current- constant voltage(CC-CV) [1,2,3]. In this technique, the battery is first charged to some specified constant current set by the manufacturer whose value ranges from 0.5 to 1 C (Coulomb).

What is the charging capacity of a lithium ion battery?

The charging capacity of 1 C is 1.162 Ah, beyond 80% of battery capacity, and the other charging rates only need to recover the rest of capacity at 25&#176;C. While the high charging rate does not work well with temperature decreasing, the charging current rate with the maximum charging capacity of 0.28 Ah is 0.5 C at 0&#176;C.

How does CCCV charging strategy affect battery temperature?

However, because the minimum-time charging strategy involved fast switching to a low current, the battery temperature decreased faster than that in the case of the 1C CCCV charging strategy. Fig. 11. Comparison of the CCCV charging strategies: (a) temperature; (b) current; (c) terminal voltage. 4.2. Minimum-aging charging strategy

Charging the Li-ion battery with constant current and constant voltage (CC-CV) strategy at -10°C can only reach 48.47% of the normal capacity. To improve the poor charging characteristic at low temperature, the
