

The use of both capacitive and inductive devices in distribution systems leads to resonance phenomena, resulting in extremely high or low impedance values. These variations in impedance modify the current and voltage in the distribution system. Here we will discuss only parallel-resonance phenomena, which are the most frequent.

voltage, the capacitors draw an overcurrent due to harmonics that could seriously damage them, especially if there is a series or parallel resonance phenomenon occuring at a harmonic frequency. In order to protect capacitors against harmon-ics, the installation of a detuning reactor in se-ries with the capacitor is strongly recommend-ed. This ...

At low frequencies, a low-value current is in the circuit, with an angle close to 90 (the circuit has a capacitive character). At large frequencies, a low-value current is delayed by a voltage of at ...

Voltage change: Individual components experience voltages higher than the source voltage at resonance. Phase Shift: In series resonance circuit voltage and current are in phase while in a parallel resonance circuit they are 180 degrees out of phase. Types Of Resonance . Series Resonance; Parallel Resonance

The electrical resonance phenomenon (also called anti-resonance in that the voltages are in anti-phase) occurs if the voltage at the terminals of the capacitance and those at the terminals of the inductance compensate one another exactly.

At resonance, the current flowing in the circuit for a fixed input voltage V is determined only by R, whereas the resonant frequency is determined only by L and C.

Example 2 demonstrates that at resonance, the voltages across the capacitor and inductor become much greater than the supply voltage. The voltage across the resistance (V R) is, of course, in phase with the circuit ...

Generally, harmonic resonance is a steady-state phenomenon triggered by an event in which the harmonic source changes or the source impedance or ca-pacitor size changes, such as if ...

As expected, the voltage (green trace) reaches maximum when the capacitor and inductor currents are zero (red and purple traces) and zero volts when the currents are maximum. The energy reaches a peak in one element while it is zero in the other.

This paper proposes a new capacitor protection for resonant harmonic loads by applying a low capacity power converter to act as a virtual harmonic resistor to damp the resonance effect at...

At low frequencies, a low-value current is in the circuit, with an angle close to 90 (the circuit has a capacitive character). At large frequencies, a low-value current is delayed by a voltage of at close to 90 (then the circuit has inductive character). At the resonant frequency f = fr, the reactance values XL and XC are equal

Finally, low-frequency transients are frequently encountered in sub-transmission and distribution systems and are caused by ferroresonance, a nonlinear form of resonance in electrical systems [51 ...
