

# The role of common lithium battery negative electrode materials

What is negative electrode material in lithium ion battery?

The negative electrode material is the main body of lithium ion battery to store lithium, so that lithium ions are inserted and extracted during the charging and discharging process.

Can electrode materials be used for next-generation batteries?

Ultimately, the development of electrode materials is a system engineering, depending on not only material properties but also the operating conditions and the compatibility with other battery components, including electrolytes, binders, and conductive additives. The breakthroughs of electrode materials are on the way for next-generation batteries.

What is a negative electrode in a battery?

In commonly used batteries, the negative electrode is graphite with a specific electrochemical capacity of 370 mA h/g and an average operating potential of 0.1 V with respect to Li/Li<sup>+</sup>. There are a large number of anode materials with higher theoretical capacity that could replace graphite in the future.

Why are graphitized carbon electrodes important for Li-ion batteries?

Graphitized carbons have played a key role in the successful commercialization of Li-ion batteries. The physicochemical properties of carbon cover a wide range; therefore, identifying the optimum active electrode material can be time consuming.

Why is graphite electrode used in lithium ion batteries?

Graphite (C) has good conductivity, high specific capacity and low lithium impingement potential, graphite electrode has a suitable charge-discharge platform and cycle performance, so it is the most widely used anode of lithium-ion batteries.

Are commercial lithium-ion battery binders better than graphite electrodes?

Commercial lithium-ion battery binders have been able to meet the basic needs of graphite electrode, but with the development of other components of the battery structure, such as solid electrolyte and dry electrode, the performance of commercial binders still has space to improve.

A typical contemporary LIB cell consists of a cathode made from a lithium-intercalated layered oxide (e.g., LiCoO<sub>2</sub>, LiMn<sub>2</sub>O<sub>4</sub>, LiFePO<sub>4</sub>, or LiNi<sub>x</sub>Mn<sub>y</sub>Co<sub>1-x</sub>O<sub>2</sub>) and mostly graphite anode with an organic electrolyte ...

Commercial Battery Electrode Materials. Table 1 lists the characteristics of common commercial positive and negative electrode materials and Figure 2 shows the voltage profiles of selected electrodes in half-cells with lithium anodes. Modern cathodes are either oxides or phosphates containing first row transition metals.

Two types of solid solution are known in the cathode material of the lithium-ion battery. One type is that two end members are electroactive, such as  $\text{LiCo}_x\text{Ni}_{1-x}\text{O}_2$ , which is a solid solution composed of  $\text{LiCoO}_2$  and  $\text{LiNiO}_2$ . The other type has one electroactive material in two end members, such as  $\text{LiNiO}_2$ - $\text{Li}_2\text{MnO}_3$  solid solution.  $\text{LiCoO}_2$ ,  $\text{LiNi}_{0.5}\text{Mn}_{0.5}\text{O}_2$ ,  $\text{LiCrO}_2$ , ...

Negative electrode is the carrier of lithium-ions and electrons in the battery charging/discharging process, and plays the role of energy storage and release. In the battery cost, the negative electrode accounts for about 5-15%, and it is one of the most important raw materials for LIBs.
