

What is a film capacitor?

Film Capacitor is one of the most popular and widely used capacitors. These possess a difference in their properties of dielectric. In the modern type of film capacitor, there is the 'direct electrical connection' establishment with the electrodes that are present on both the windings. This keeps the path of the current to the electrode very short.

How to choose a film capacitor?

A Film Capacitor can be chosen its film based on the requirement of stability and where the cost is concerned. A capacitor whose dielectric is chosen is of the 'Film' type. This type possesses stable behavior, low manufacturing cost. These types of capacitors are defined as film capacitors.

What determines the self-inductance of a film capacitor?

The self-inductance or series inductance LS of a film capacitor is due to the magnetic field created by the current in the film metallization and the connections. It is thus determined by the winding structure, the geometric design and the length and thickness of the contact paths.

How do metalized film capacitors work?

The electrodes of metalized film capacitors consist of an extremely thin metal layer (0.02 μm to 0.1 μm) that is vacuum deposited either onto the dielectric film or onto a carrier film. The opposing and extended metalized film layers of the wound capacitor element are connected to one another by flame spraying different metals to the end-faces.

What is the difference between a film foil capacitor and a metalized capacitor?

The primary distinction between a film foil capacitor and a metalized capacitor is that the metallic electrodes are fused into either side of the dielectric plastic in the latter instead of layering. While it raises the cost and also adds a step to the production process, it has greater reliability and smaller dimensions than a film foil condenser.

What are the benefits of a film capacitor?

In the modern type of film capacitor, there is the 'direct electrical connection' establishment with the electrodes that are present on both the winding's. This keeps the path of the current to the electrode very short. This capacitor has various benefits like it has very low ESR (ohmic resistance) and ESL (Parasitic Inductance).
